

Float and Character Datatype

- A decimal number is not stored inside the memory but they represent decimal number . so, in order to avoid it we move the decimal point that means we float that point hence we call it as float type
- The float number is stored in binary form and its conversion is done as follows the standard used for conversion is IEEE 754 format

Float

163.52

$163.52 \times 100 / 100$

$16352 \times 1 / 100$

16352×10^{-2}

- When you want to precise value in decimal point then we can go for double because in some cases detail decimal value is needed for accurate result.
- It supports upto 14 numbers under

Char :

- The computer doesn't support alphabets so we use numeric code for these characters . So, those codes are called ASCII codes
- This is supported by other programming language
- Not only for English but they are codes available for every natural language in the world as internet supports various languages so must the machines too these codes are called unicodes
- Therefore ASCII codes comes under Unicode
